Class 3b: Review of concepts in Probability and Statistics

Business Forecasting

Confidence Intervals

Confidence Intervals

- We calculated the mean price in our sample
- How confident are we that our estimate is close to the parameter's value?
- Confidence intervals measure uncertainty around the estimate

Confidence Intervals

- Mean price was 1245.43
- Is it reasonable to think true average price in population is 1100? What about 2000?
- Suppose that we calculated the confidence interval to be:

$$\{1086.64, 1404.22\}$$

  - Where are these numbers coming from?

1. The sampling distribution of the sample mean tells us how likely we are to get a point estimate which is far away from the true mean

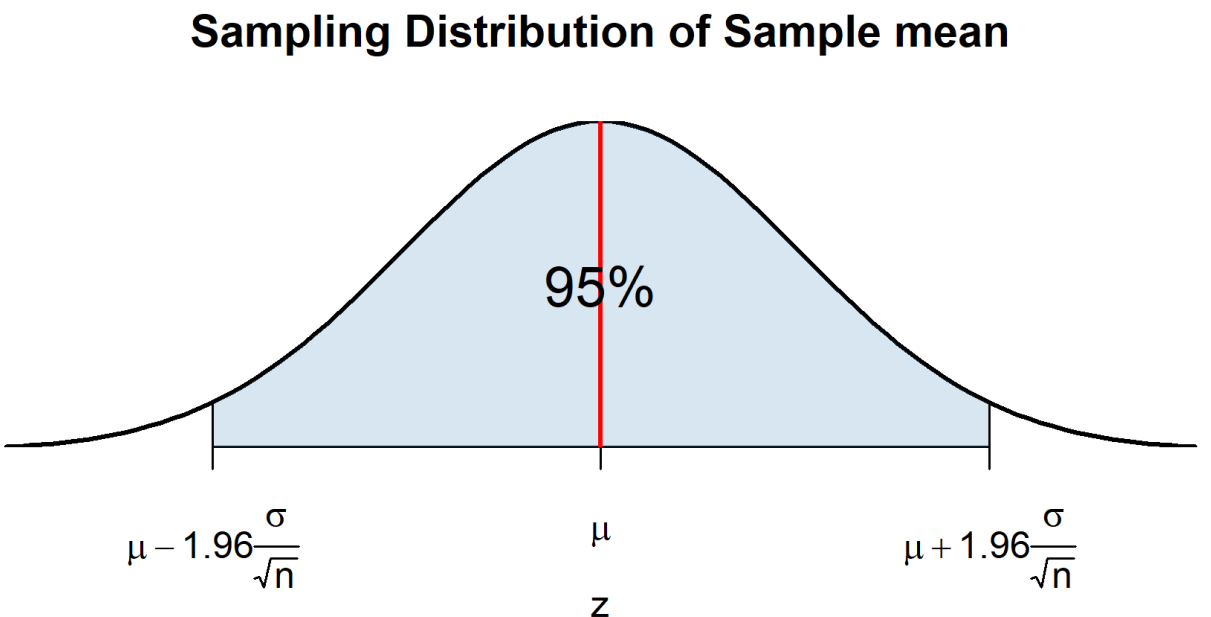
2. The confidence interval uses this property of the sampling distribution to tell us where the true mean might be

   - Let's go through these statements 1-by-1

Sampling distribution

Q: How likely is it that a sample mean is far away from the true mean?

- Consider a hypothetical sampling distribution of a sample mean
  - Reminder: $\bar{x} \sim \mathcal{N}(\mu, \frac{\sigma}{\sqrt{n}})$
  - If we draw samples repeatedly, 95% of their means will be within the shaded area
- Why 1.96?

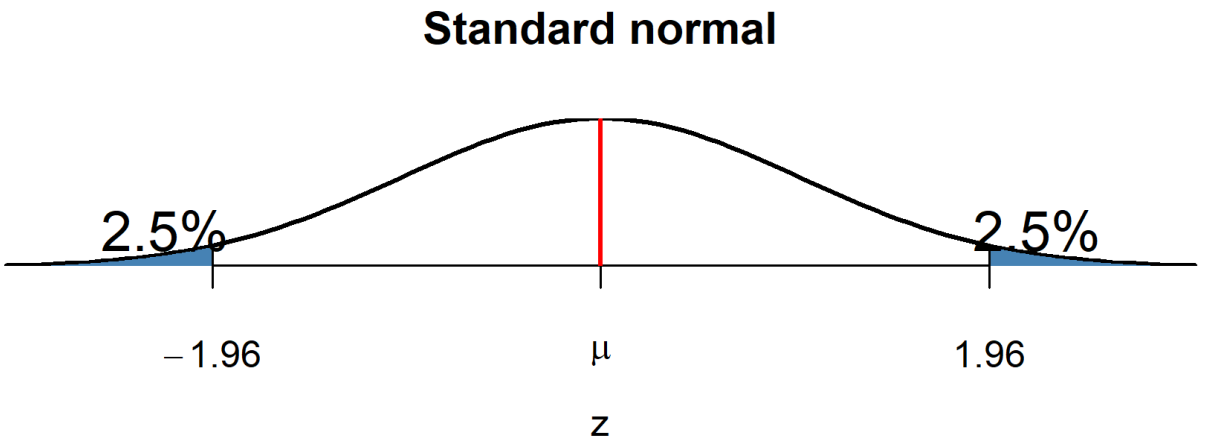


Sampling distribution

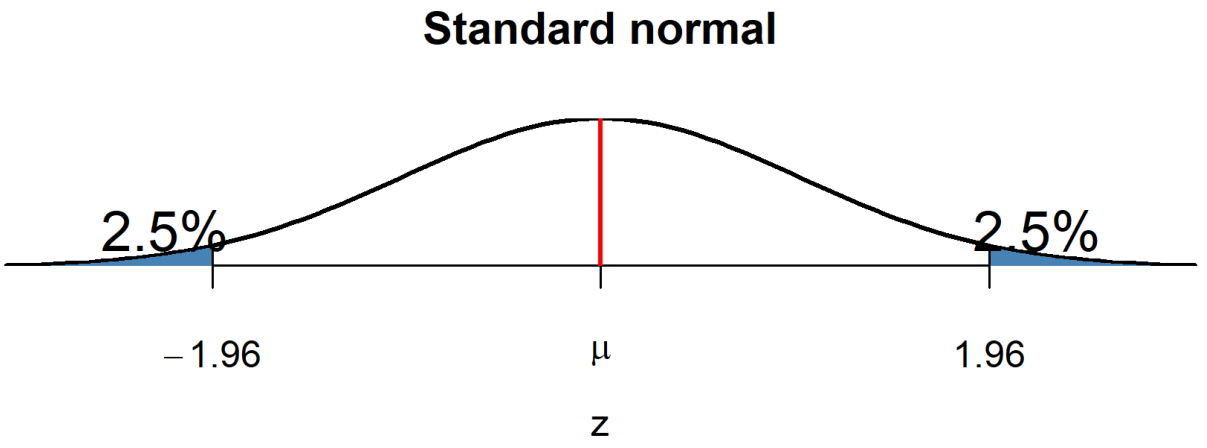
- Assume we have $n > 30$
  - CLT applies and $\bar{X} \sim N(\mu_X, \frac{\sigma_X}{\sqrt{n}})$
- We want to find k_1 and k_2, such that:
  - $P(k_1 < \bar{X} < k_2) = 0.95$, so
  - $P(\bar{X} < k_1) = 0.025$ and $P(\bar{X} > k_2) = 0.025$ (or $P(\bar{X} < k_2) = 0.975$)
  - Trick is to standardize the variable:

$$P(\bar{X} < k_2) = P(\bar{X} - \mu_X < k_2 - \mu_X) = P(\underbrace{\frac{\bar{X} - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}}_{Z \sim N(0,1)} < \underbrace{\frac{k_2 - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}}_{k_2'})$$

In probability tables, we can find k_2', such that $P(Z < k_2') = 0.975$



- It's 97.5% quantile of standard normal: $k_2' = v^Z_{0.975} = 1.96$.
  $P(Z < v_{0.975}) = P(Z < 1.96) = 0.975$
- Let's go back to $k_2' = \frac{k_2 - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}$, from which we can back-out k_2
  - $k_2 = \mu_X + k_2' \frac{\sigma_X}{\sqrt{n}} = \mu_X + 1.96 \frac{\sigma_X}{\sqrt{n}}$
- By symmetry of normal, $k_1' = -k_2'$, so $k_1 = \mu_X + \frac{\sigma_X}{\sqrt{n}} k_1' = \mu_X - 1.96 \frac{\sigma_X}{\sqrt{n}}$



- Another way to see it:
  - Our variable is a linear transformation of a standard normal: $\bar{X} = \mu_X + \frac{\sigma_X}{\sqrt{n}} Z$
  - So its percentiles are linear transformation of st.nor. quantiles: $v^{\bar{X}}_{0.975} = \mu_X + \frac{\sigma_X}{\sqrt{n}} v^{Z}_{0.975}$

Yet another way to see it

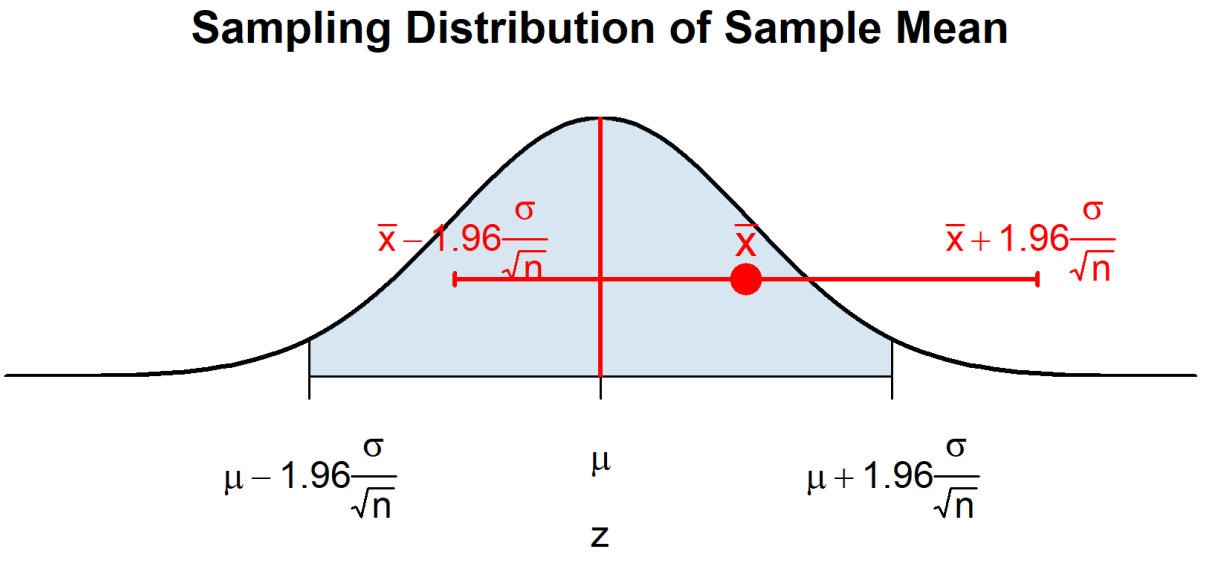
$$
\begin{aligned}
0.95 &= P(-1.96 < Z < 1.96) \\
&= P(z_{-\frac{\alpha}{2}} < Z < z_{\frac{\alpha}{2}}) \\
&= P(z_{-\frac{\alpha}{2}} < \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} < z_{\frac{\alpha}{2}}) \\
&= P(z_{-\frac{\alpha}{2}}\sigma/\sqrt{n} < \bar{X} - \mu < z_{\frac{\alpha}{2}}\sigma/\sqrt{n}) \\
&= P(\mu - z_{-\frac{\alpha}{2}}\sigma/\sqrt{n} < \bar{X} < \mu + z_{\frac{\alpha}{2}}\sigma/\sqrt{n})
\end{aligned}
$$

- Theoretically, CLT theorem guarantees that $\frac{\bar{X}-\mu}{\sigma/\sqrt{n}}$ is standard normal
- What happens if you do not know σ?
- In large sample, $s \to \sigma$, so $\frac{\bar{X}-\mu}{s/\sqrt{n}} \to N(0,1)$
- So in large samples, standardized sample mean (with estimated standard deviation) will also have normal distribution
- You man need a bit higher n to ensure $s \to \sigma$

Sampling distribution

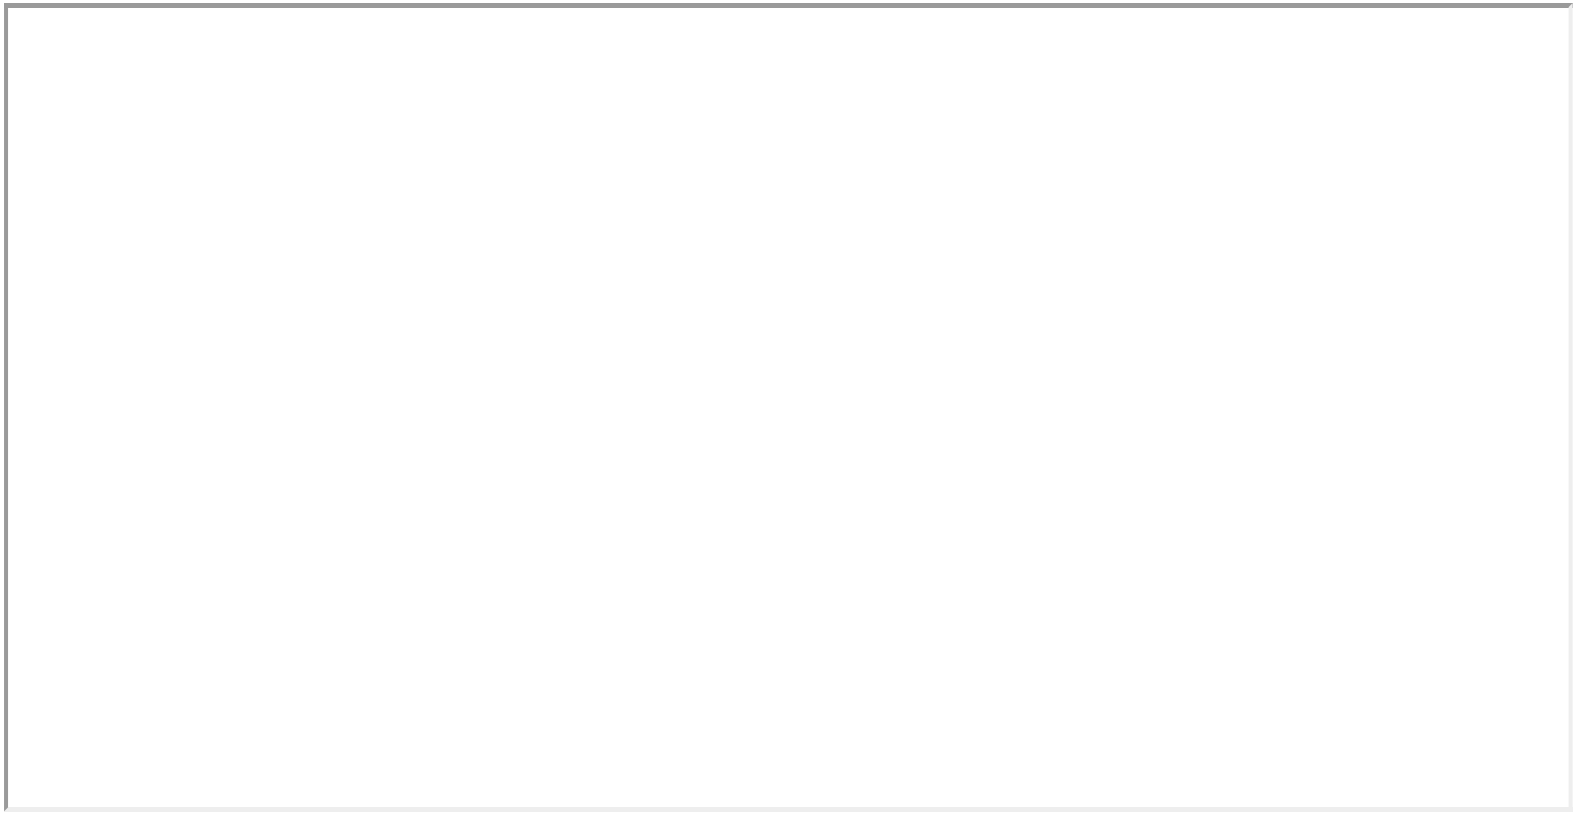
Q: How far is the sampled mean from the true mean?

- Hence 95% of the draws of sample means will be within distance of $1.96\frac{\sigma_X}{\sqrt{n}}$ to the true parameter
- There is only 5% chance that we have draw sample weird enough that $\bar{X}$ is further from μ_X by more than $1.96\frac{\sigma_X}{\sqrt{n}}$
- Confidence interval of $\bar{X}$ will cover μ_X as long as $|\mu_X - \bar{X}| < 1.96\frac{\sigma_X}{\sqrt{n}}$



Sampling distribution

- Suppose we draw many samples from the same distribution
- For each sample we compute the sample mean and we construct the interval
- 95% of them will cover the true population mean!



Source: [https://seeing-theory.brown.edu/frequentist-inference/index.html#section2)

Calculation Procedure

Use this procedure if $n > 30$

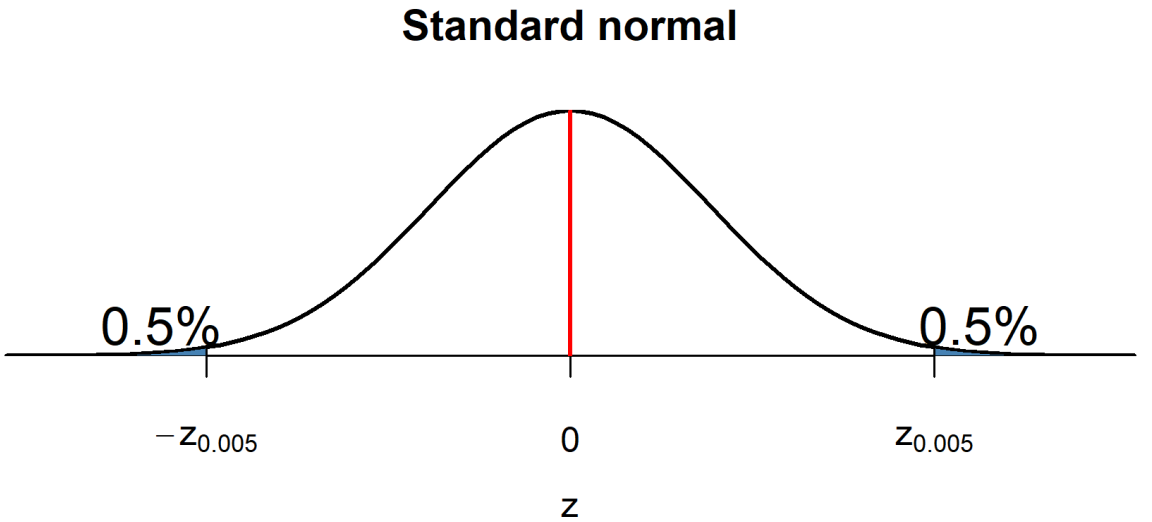
1. Take an IID sample
2. Calculate mean $\bar{x}$ and standard deviation s in your sample
   - Standard Error is standard deviation of the estimator $SE = \frac{s}{\sqrt{n}}$
3. Pick confidence level (usually 90,95,99%)
   - We typically denote the confidence level $1 - \alpha$
   - α is probability of making a Type 1 error (more about it later)
   - Example: if confidence level is 95%, $\alpha = 0.05$
4. Find the corresponding critical values $z_{\frac{\alpha}{2}}$
   - Critical values are such that $P(-z_{\frac{\alpha}{2}} < Z < z_{\frac{\alpha}{2}}) = 1 - \alpha$
   - Example: if confidence level is 95%, $z_{\frac{\alpha}{2}} = z_{0.025} = 1.96$
5. Construct the confidence interval as:

$$\{\bar{x} - z_{\frac{\alpha}{2}} * \underbrace{\frac{s}{\sqrt{n}}}_{SE}, \bar{x} + z_{\frac{\alpha}{2}} * \frac{s}{\sqrt{n}}\}$$

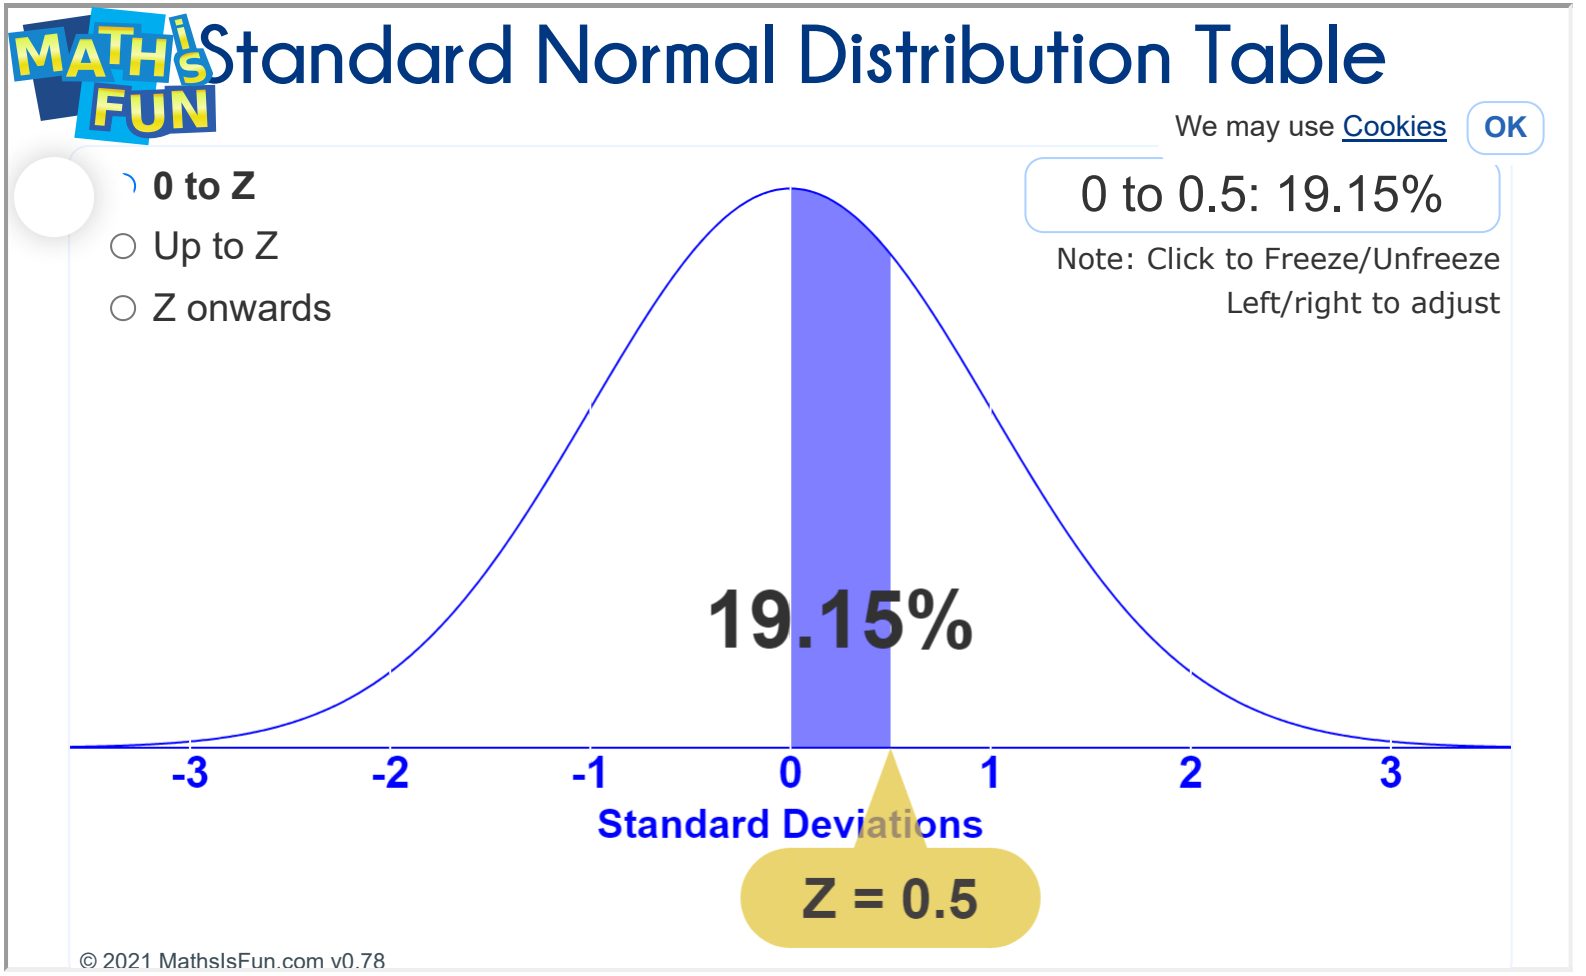
Finding Critical Values

- Suppose confidence interval is 99%.
- Then $\alpha = 0.01$
- We are looking for $z_{\frac{\alpha}{2}}$ such that:

$$P(-z_{\frac{\alpha}{2}} < Z < z_{\frac{\alpha}{2}}) = 0.99$$



$$P(Z > z_{0.005}) = 0.005 \qquad \text{or} \qquad P(Z < z_{0.005}) = 0.995$$



Source: [https://www.mathsisfun.com/data/standard-normal-distribution-table.html)

Finding Critical Values

$P(Z < z_{\frac{\alpha}{2}}) = 0.995$ $z_{\frac{\alpha}{2}}$, is 99.5% quantile of standard normal $\rightarrow z_{\frac{\alpha}{2}} = 2.58$

Constructing CI: example

Let's calculate 90% CI for average price of listing with grade>4.5

1. Take an IID sample
   - $n = 100$ ✓
2. Calculate mean $\bar{x}$ and standard deviation s
   - $\bar{x} =$ 1245.43 and $s =$ 961.9
3. Pick confidence level
   - We pick 90%, so $\alpha = 0.1$
4. Find the corresponding critical values $z_{\frac{\alpha}{2}}$
   - Find $z_{\frac{\alpha}{2}}$ such that $P(Z > z_{\frac{\alpha}{2}}) = 0.05$ (or $P(Z < z_{\frac{\alpha}{2}}) = 0.95$)
   - $z_{0.05} = 1.65$
5. Construct the confidence interval as:

$$\{\bar{x} - z_{\frac{\alpha}{2}} * \frac{s}{\sqrt{n}}, \bar{x} + z_{\frac{\alpha}{2}} * \frac{s}{\sqrt{n}}\}$$

$$\{1245.43 - 1.65\frac{961.9}{\sqrt{100}}, 1245.43 + 1.65\frac{961.9}{\sqrt{100}}\}$$

Interpreting confidence intervals

$$CI_{90} = \{1086.64, 1404.22\}$$

How do we interpret a 90% confidence interval we computed?

- **Correct Interpretation**
  - We are 90% confident that the interval captures the true mean
  - We are 90% confident that the true mean price of listings with grade>4.5 is between 1086.64 and 1404.22
- **Incorrect**
  - With 90% probability the true mean is between 1086.64 and 1404.22
    - Computed interval is not-random and true mean is not random, so can't make probabilistic statements.
    - Interval is a function of random variables only **before** we draw a sample and make any computation.
    - After we have a sample, nothing is random. The true mean is either between 1086.64 and 1404.22 or not.

Shape of confidence intervals

Confidence intervals $\{\bar{x} - z_{\frac{\alpha}{2}} * \frac{s}{\sqrt{n}}, \bar{x} + z_{\frac{\alpha}{2}} * \frac{s}{\sqrt{n}}\}$ are wider when:

- Confidence level is higher (99% is wider than 90%)
- When n is small
- When σ is large

Practice

Suppose we want to know what is the average commute time for ITAM students. We take a sample of 60 students. We calculate sample mean to be $\bar{x} = 23$ and sample standard deviation to be $\sum x^2 = 35516$. Calculate 99% confidence interval and say whether interpratation is correct:

Practice

Suppose we want to know what is the average commute time for ITAM students. We take a sample of 60 students. We calculate sample mean to be $\bar{x} = 23$ and sample standard deviation to be $\sum x^2 = 35516$. Calculate 99% confidence interval and say whether interpratation is correct:

We are 99% confident that the average commute of these 60 students is between (20.3364, 25.6636)	0
We are 99% confident that the average commute of all ITAM students is between (20.3364, 25.6636) ✓	0
A 95% confidence interval would be wider	0
99% of random samples would have mean between (20.3364, 25.6636)	0
99% of random samples would capture the true mean ✓	0
With 99% probability true mean is between this and this (20.3364, 25.6636)	0

What critical values?

When should we use critical values from Normal Distribution?

1. Original distribution (of X) is not normal:
    - If $n > 30$- use critical values from normal distribution (40 if σ unknown)
    - If $n < 30$ - you are screwed
2. Original distribution (of X) is normal:
    - If you know σ, you can use critical values from normal (n doesn't matter)
        - If X is normal, then use σ instead of s and $\frac{\bar{X}-\mu}{\frac{\sigma}{\sqrt{n}}} \sim N(0,1)$
    - If you don't know σ but $n > 40$, you can use critical values from normal
        - CLT kicks in
    - If you don't know σ and $n < 40$, you use critical values from student's t.
        - $\frac{\bar{X}-\mu}{\frac{s}{\sqrt{n}}}$ is not normal. s is not a good approx. of σ when n is low

What's Student's t?

If $X_1, X_2, \ldots, X_n$ are i.i.d. from $N(\mu, \sigma)$, then

$$T = \frac{\bar{X} - \mu}{s/\sqrt{n}}$$

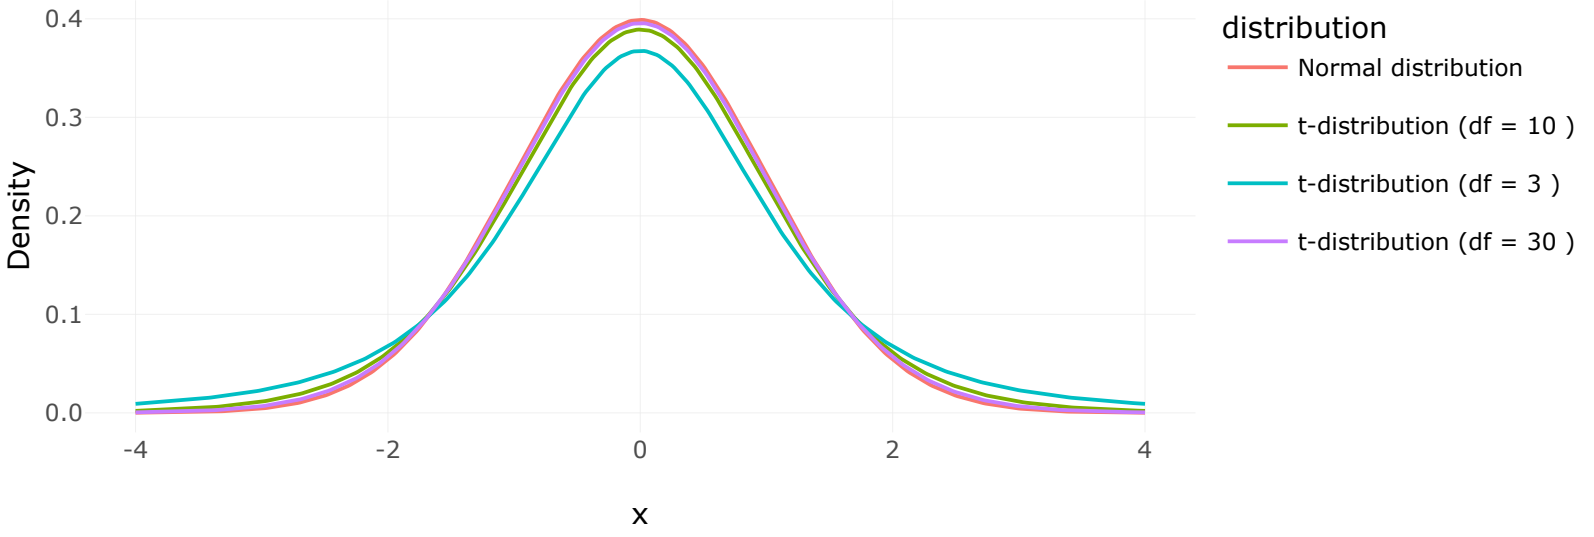
Where s is sample standard deviation.

T has a student's t distribution with n-1 degrees of freedom

$$T \sim t_{n-1}$$

What's Student's t?

- Bell shaped and symmetric around 0
- More spread out - heavier tails, more uncertainty (because we don't know standard deviation)
- Shape determined by the degrees of freedom.
  - As n increases (and hence degrees of freedom), it tends to standard normal (as it should by CLT!)
  - Less uncertainty because we are better at estimating standard deviation

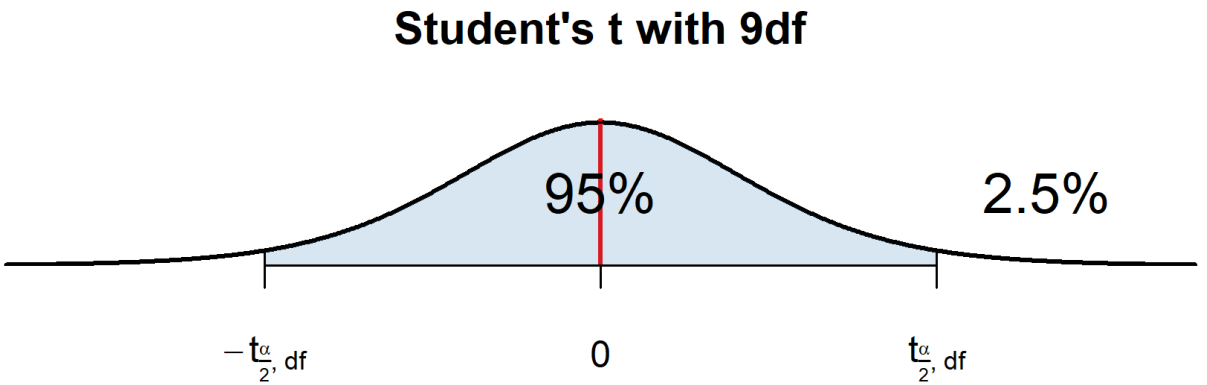


Student's t critical values

Finding critical values for student's t distribution:

1. Determine what is the right number of degrees of freedom ($n-1$)!
2. Determine what's your confidence level and your $(1-\alpha)$
   - From this figure out $\alpha/2$
3. Find the percentile such that

$$P(T > t_{\frac{\alpha}{2},\underbrace{n-1}_{d.f.}}) = \frac{\alpha}{2} \qquad \text{or} \qquad P(T < t_{\frac{\alpha}{2},n-1}) = 1 - \frac{\alpha}{2}$$



Example

- $n = 10 \rightarrow df = 9$
- Confidence level is 95% $\rightarrow 1 - \alpha = 0.95$ and $\frac{\alpha}{2} = 0.025$
- What's $t_{0.025,9}$ such that $P(T < t_{0.025,9}) = 0.975$

5. Distribución t de Student

$$T \sim t_\nu$$

siendo ν los grados de libertad.

$$p = P(T \leq t) = \int_{-\infty}^{t} \phi_T(u)du = 1 - \alpha$$

donde

$$\phi_T(u) = \frac{1}{\sqrt{\nu\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \left(1 + \frac{u^2}{\nu}\right)^{-\frac{\nu+1}{2}}$$

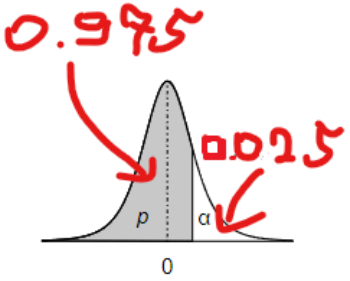


Tabla 5. Valores críticos $t_{(\alpha;\nu)}$ de la distribución t de Student.

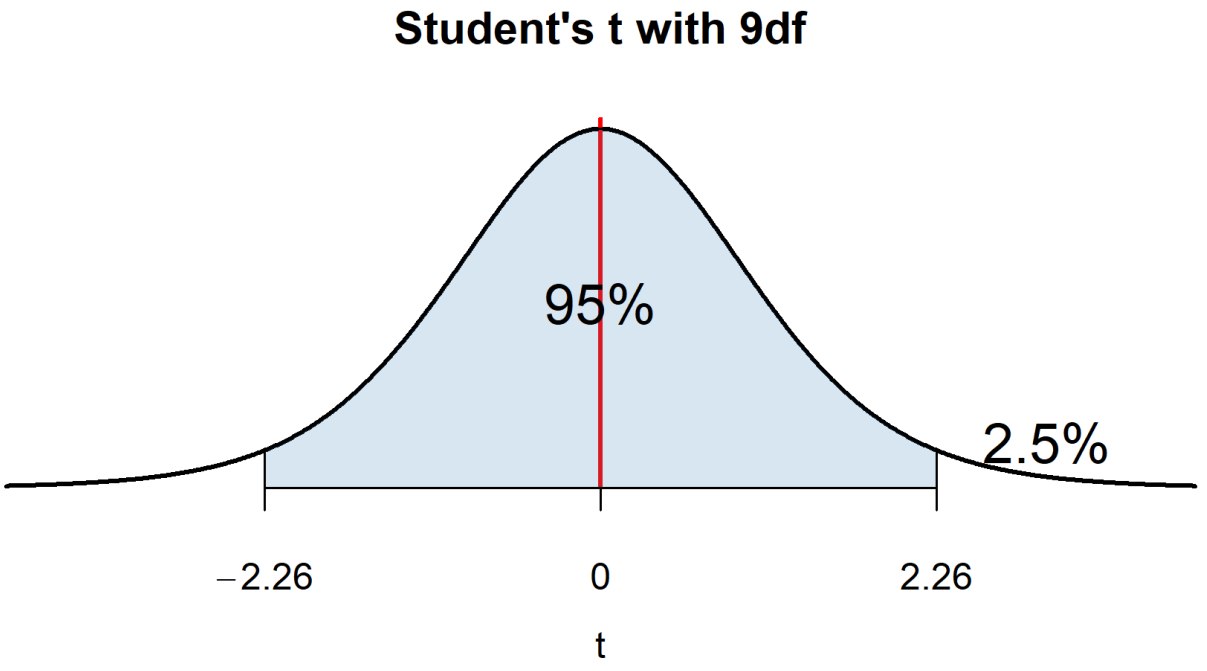
df

- $n = 10 \rightarrow df = 9$
- Confidence level is 95% $\rightarrow 1 - \alpha = 0.95$ and $\frac{\alpha}{2} = 0.025$
- What's $t_{0.025,9}$ such that $P(T < t_{0.025,9}) = 0.975$



- Once we have critical value, we construct the CI as before:

$$\{\bar{x} - t_{\frac{\alpha}{2},n-1} * \frac{s}{\sqrt{n}}, \bar{x} + t_{\frac{\alpha}{2},n-1} * \frac{s}{\sqrt{n}}\}$$

Practice:

Your company implemented free shipping for a random group of customers. They want to know whether it increased spending. Here is your data:

$157.80, $192.45, $210.20, $175.60, $198.30, $180.90, $205.75, $185.20, $177.40, $195.60

a) Calculate 90% confidence interval. What assumptions you need?

- Hint 1: $\sum_i x_i = 1869.80$
- Hint 2: $\sum_i x_i^2 = 361752.55$

b) Average spending without free shipping is $182, can say anything about whether free shipping increased spending?

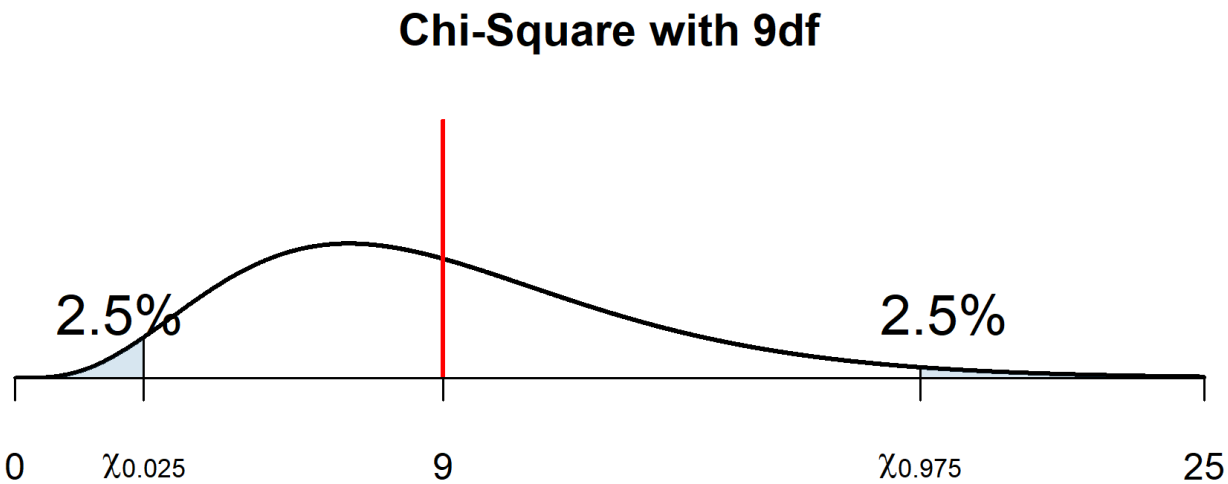
Confidence Intervals for Variance

- Suppose $X_1, X_2, \ldots X_n$ come from normal distribution
- The sampling distribution of the sample variance $S^2 = \frac{\sum_i (X_i - \bar{X})^2}{n-1}$ is:

$$\frac{(n-1)S^2}{\sigma^2} \sim \chi_{n-1}$$

- We will use the fact that:

$$P(\chi_{0.025,n-1} < \frac{(n-1)S^2}{\sigma^2} < \chi_{0.975,n-1}) = 0.95$$



Confidence Intervals for Variance

How we use it to construct the confidence interval?

$$
\begin{aligned}
0.95 &= P(\chi_{0.025,n-1} < \frac{(n-1)S^2}{\sigma^2} < \chi_{0.975,n-1}) \\
&= P(\frac{1}{\chi_{0.975,n-1}} < \frac{\sigma^2}{(n-1)S^2} < \frac{1}{\chi_{0.025,n-1}}) \\
&= P(\frac{(n-1)S^2}{\chi_{0.975,n-1}} < \sigma^2 < \frac{(n-1)S^2}{\chi_{0.025,n-1}})
\end{aligned}
$$

So more generally, the confidence interval for the sample variance is

$$
CI_{1-\alpha} = \{\frac{(n-1)S^2}{\chi_{1-\frac{\alpha}{2},n-1}}, \frac{(n-1)S^2}{\chi_{\frac{\alpha}{2},n-1}}\}
$$

- Where $\chi_{1-\frac{\alpha}{2},n-1}$ and $\chi_{\frac{\alpha}{2},n-1}$ are quantiles of χ_{n-1} distribution, such that $P(X < \chi_{1-\frac{\alpha}{2},n-1}) = 1 - \frac{\alpha}{2}$ and $P(X < \chi_{\frac{\alpha}{2},n-1}) = \frac{\alpha}{2}$
- You can read them off the tables

Practice

Suppose you produce sausages. As a quality control, you measure the level of fat in your sausages. You take a random sample of 12 sausages and you find the variance of 20 ($grams^2$). Find 99% confidence interval for the variance. What assumptions you need?
